

Esewa Customer, Risk and Growth Analysis Report

About this report

Leadership raised six concerns: suspicious activity, rising acquisition costs, weak retention of new users, KYC drop-off, failed payments, and uneven customer value. This report answers them in plain terms. Full technical detail is in the accompanying notebook and detailed report.

No dataset was provided, so I built a realistic test dataset: 1 million users and 25 million transactions over two years, modelled on a digital wallet like ours. It behaves like real payment data, including errors and gaps, which I found and cleaned first (about 25,000 duplicate records were removed so volumes are not overstated). The numbers describe no real company; they show how the same analysis would work on our real data.

1. First payments fail too often, and it costs us customers

About 1 in 7 first payments fails. By a customer's fourth payment, failures drop to about 1 in 25. The risk sits exactly where the customer is least committed.

Failure rate by payment number in a customer's life.

When the first payment works, 96% of customers come back for a second. When it fails, only 74% do. One bad first experience loses roughly one in five new customers, after we already paid to bring them in.

A failed first transaction costs ~21 points of early retention

Share of customers who make a second payment.

What to do: Make the first payment the most reliable moment in the product. Fix the technical causes, and add an instant retry with a small apology credit when it fails.

2. We lose customers before they even start

Out of every 100 signups, 21 never begin identity verification (KYC), 29 never complete it, and 3 never make a single payment. Marketing money is leaking at onboarding, not at advertising.

Onboarding funnel: where users are lost

Where signups drop out. Customers can transact before verifying, within limits.

What to do: Simplify the verification steps and track time-to-verify as a standard KPI.

3. The March failure spike was a system problem, not fraud

For two weeks in March 2026, failures jumped, but only on two payment rails: merchant QR and bank transfers. Everything else stayed normal, and so did amounts and volumes. That points to a payment gateway problem, not criminals and not bad data.

Weekly failure rate by product. The spike touches exactly two rails.

What to do: Run an incident review with the gateway provider and agree service levels before volume grows further.

4. There are signs of suspicious activity

Bank transfers cluster just below Rs 100,000, the reporting threshold. Splitting transfers to stay under a threshold is a known money-laundering pattern. Separately, a small group of accounts (about 5% of users) fails almost half its payments and is almost never identity-verified.

Bank transfers pile up just under the Rs 100,000 threshold.

What to do: Send these accounts to compliance review, and cap what unverified accounts can do.

5. Our customers are six different groups, not one

Segment sizes

Customers by segment.

Group	Size	Who they are	What to do
High-Value	14%	Top spenders, use us almost daily	Protect them: priority support, perks, bundles
Power	40%	Constant use, moderate spend	Turn into advocates: referral rewards
Standard	28%	Occasional use	Encourage a second service
Dormant	10%	Were active, gone quiet	Win-back offers, but test first: many came only for cashback
Risky	5%	Many failures, unverified	Compliance review and account limits
Never started	3%	Signed up, never paid	Nudge within days; the first payment must succeed

The six customer groups and the action each one calls for.

The most valuable 14% carry most of the money. Keeping them costs far less than replacing them.

6. The next few months

Monthly payment volume has grown to about Rs 6 billion. Extending the recent trend suggests continued growth; treat the dashed line below as a planning baseline, not a precise forecast. Plan capacity and cashback budgets for rising volume. March already showed what happens when reliability lags growth.

TPV trend with a simple baseline projection (not a forecast model)

Monthly payment volume, with a simple three-month baseline (dashed).

7. PowerBI Dashboard

The Power BI dashboard shows all of the above interactively across four pages: overall performance, onboarding, risk, and customers, filterable by month, province and segment. One naming note: we show payment volume (TPV), not revenue. Revenue would be our fees on that volume, which this data does not model.

The fine print

The data is synthetic, built for this assessment; the findings demonstrate method, not facts about a real market. On real data, the link between a failed first payment and customer loss should be confirmed with a proper study before large spending, and the outlook should be replaced with a tested forecast.
